Sending RTP Control Protocol (RTCP) Feedback for Congestion Control in
Interactive Multimedia Conferences
draft-ietf-rmcat-rtp-cc-feedback-11

Abstract

This memo discusses the rate at which congestion control feedback can be sent using the RTP Control Protocol (RTCP) and its suitability for implementing congestion control for unicast multimedia applications.

Status of This Memo

This Internet-Draft is submitted in full conformance with the provisions of BCP 78 and BCP 79.

Internet-Drafts are working documents of the Internet Engineering Task Force (IETF). Note that other groups may also distribute working documents as Internet-Drafts. The list of current Internet-Drafts is at <https://datatracker.ietf.org/drafts/current/>.

Internet-Drafts are draft documents valid for a maximum of six months and may be updated, replaced, or obsoleted by other documents at any time. It is inappropriate to use Internet-Drafts as reference material or to cite them other than as "work in progress."

This Internet-Draft will expire on April 10, 2023.

1. Introduction

The deployment of WebRTC systems [RFC8825] has resulted in high-quality video conferencing seeing extremely wide use. To ensure the stability of the network in the face of this use, WebRTC systems need to use some form of congestion control for their RTP-based media traffic [RFC2914], [RFC8085], [RFC8083], [RFC8834], allowing them to adapt and adjust the media data they send to match changes in the available network capacity. In addition to ensuring the stable operation of the network, such adaptation is critical to ensuring a good user experience, since it allows the sender to match the media to the network capacity, rather than forcing the receiver to compensate for uncontrolled packet loss when the available capacity is exceeded.

To develop such congestion control, it is necessary to understand the sort of congestion feedback that can be provided within the framework of RTP [RFC3550] and the RTP Control Protocol (RTCP). It then becomes possible to determine if this is sufficient for congestion control, or if some form of RTP extension is needed.

This memo considers unicast congestion feedback that can be sent using RTCP under the RTP/SAVPF profile [RFC5124] (the secure version of the RTP/AVPF profile [RFC4585]). This profile was chosen as it forms the basis for media transport in WebRTC [RFC8834] systems. Nothing in this memo is specific to the secure version of the profile, or to WebRTC, however. It is also assumed that the congestion control feedback mechanism described in [RFC8888], and common RTCP extensions for efficient feedback [RFC5506], [RFC8108], [RFC8861], and [RFC8872] are used.

2. Considerations for RTCP Feedback

Several questions need to be answered when providing RTCP feedback for congestion control purposes. These include:

- o How often is feedback needed?
- o How much overhead is acceptable?
- o How much, and what, data does each report contain?

The key question is how often does the receiver need to send feedback on the reception quality it is experiencing and hence the congestion state of the network?

Widely used transport protocols, such as TCP, send acknowledgements frequently. For example, a TCP receiver will send an acknowledgement at least once every 0.5 seconds or when new data equal to twice the maximum segment size has been received [I-D.ietf-tcpm-rfc793bis]). That has relatively low overhead when traffic is bidirectional and acknowledgements can be piggybacked onto return path data packets. It can also be acceptable, and can have reasonable overhead, to send separate acknowledgement packets when those packets are much smaller than data packets.

Frequent acknowledgements can become a problem, however, when there is no return traffic on which to piggyback feedback, or if separate feedback and data packets are sent and the feedback is similar in size to the data being acknowledged. This can be the case for some forms of media traffic, especially for voice over IP flows, leading to high overhead when using a transport protocol that sends frequent feedback. Approaches like in-network filtering of acknowledgements that have been proposed to reduce acknowledgement overheads on highly asymmetric links (e.g., as mentioned in [RFC3449]) can also reduce the feedback frequency and overhead for multimedia traffic, but this so-called "stretch-ACK" behaviour is non-standard and not guaranteed.

Accordingly, when implementing congestion control for RTP-based multimedia traffic, it might make sense to give the option of sending congestion feedback less often than TCP does. For example, it might be possible to send a feedback packet once per video frame, or every few frames, or once per network round trip time (RTT). This could still give sufficiently frequent feedback for the congestion control loop to be stable and responsive while keeping the overhead reasonable when the feedback cannot be piggybacked onto returning data. In this case, it is important to note that RTCP can send much more detailed feedback than simple acknowledgements. For example, if it were useful, it could be possible to use an RTCP extended report

(XR) packet [RFC3611] to send feedback once per RTT comprising a bitmap of lost and received packets, with reception times, over that RTT. As long as feedback is sent frequently enough that the control loop is stable, and the sender is kept informed when data leaves the network (to provide an equivalent to ACK clocking in TCP), it is not necessary to report on every packet at the instant it is received. Indeed, it is unlikely that a video codec can react instantly to a rate change, and there is little point in providing feedback more often than the codec can adapt. This suggests that an RTP receiver needs to be configured to provide feedback at a rate that matches the rate of adaptation of the sender. In the best case, this will match the media frame rate, but might often be slower.

Reducing the feedback frequency compared to TCP will reduce feedback overhead but will lead multimedia flows to adapt to congestion more slowly than TCP, raising concerns about inter-flow fairness. Similar concerns are noted in [RFC5348], and accordingly the congestion control algorithm described therein aims for "reasonable" fairness and a sending rate that is "generally within a factor of two" of that TCP would achieve under the same conditions. It is to be noted, however, that TCP exhibits inter-flow unfairness when flows with differing round-trip times compete, and stretch acknowledgements due to in-network traffic manipulation are not uncommon and also raise fairness concerns. Implementations need to balance potential unfairness against feedback overhead.

Generating and processing feedback consumes resources at the sender and receiver. The feedback packets also incur forwarding costs, contribute to link utilization, and can affect the timing of other traffic on the network. This can affect performance on some types of network, that can be impacted by the rate, timing, and size of feedback packets, as well as by the overall volume of feedback bytes.

The amount of overhead due to congestion control feedback that is considered acceptable has to be determined. RTCP feedback is sent in separate packets to RTP data, and this has some cost in terms of additional header overhead compared to protocols that piggyback feedback on return path data packets. The RTP standards have long said that a 5% overhead for RTCP traffic is generally acceptable, while providing the ability to change this fraction. Is this still the case for congestion control feedback? Is there a desire to provide more responsive feedback and congestion control, possibly with a higher overhead? Or is lower overhead wanted, accepting that this might reduce responsiveness of the congestion control algorithm?

Finally, the details of how much, and what, data is to be sent in each report will affect the frequency and/or overhead of feedback. There is a fundamental trade-off that the more frequently feedback

packets are sent, the less data can be included in each packet to keep the overhead constant. Does the congestion control need high rate but simple feedback (e.g., like TCP acknowledgements), or is it acceptable to send more complex feedback less often? Is it useful for the congestion control to receive frequent feedback, perhaps to provide more accurate round-trip time estimates, or to provide robustness in case feedback packets are lost, even if the media sending rate cannot quickly be changed? Or is low-rate feedback, resulting in slowly responsive changes to the sending rate, acceptable? Different combinations of congestion control algorithm and media codec might require different trade-offs, and the correct trade-off for interactive, self-paced, real-time multimedia traffic might not be the same as that for TCP congestion control.

3. What Feedback is Achievable With RTCP?

The following sections illustrate how the RTCP congestion control feedback report [RFC8888] can be used in different scenarios, and illustrate the overheads of this approach.

3.1. Scenario 1: Voice Telephony

In many ways, point-to-point voice telephony is the simplest scenario for congestion control, since there is only a single media stream to control. It's complicated, however, by severe bandwidth constraints on the feedback, to keep the overhead manageable.

Assume a two-party point-to-point voice-over-IP call, using RTP over UDP/IP. A rate adaptive speech codec, such as Opus, is used, encoded into RTP packets in frames of duration T_f seconds ($T_f = 0.020s$ in many cases, but values up to $0.060s$ are not uncommon). The congestion control algorithm requires feedback every N_r frames, i.e., every $N_r * T_f$ seconds, to ensure effective control. Both parties in the call send speech data or comfort noise with sufficient frequency that they are counted as senders for the purpose of the RTCP reporting interval calculation.

RTCP feedback packets can be full, compound, RTCP feedback packets, or reduced-size RTCP packets [RFC5506]. A compound RTCP packet is sent once for every N_{rs} reduced-size RTCP packets.

Compound RTCP packets contain a Sender Report (SR) packet, a Source Description (SDS) packet, and an RTP Congestion Control Feedback (CCFB) packet [RFC8888]. Reduced-size RTCP packets contain only the CCFB packet. Since each participant sends only a single RTP media stream, the extensions for RTCP report aggregation [RFC8108] and reporting group optimisation [RFC8861] are not used.

Within each compound RTCP packet, the SR packet will contain a sender information block (28 octets) and a single reception report block (24 octets), for a total of 52 octets. A minimal SDES packet will contain a header (4 octets) and a single chunk containing an SSRC (4 octets) and a CNAME item, and if the recommendations for choosing the CNAME [RFC7022] are followed, the CNAME item will comprise a 2-octet header, 16 octets of data, and 2 octets of padding, for a total SDES packet size of 28 octets. The CCFB packets contain an RTCP header and SSRC (8 octets), a report timestamp (4 octets), the SSRC, beginning and ending sequence numbers (8 octets), and $2*Nr$ octets of reports, for a total of $20 + 2*Nr$ octets. The compound Secure RTCP packet will include 4 octets of trailer followed by an 80 bit (10 octet) authentication tag if HMAC-SHA1 authentication is used. If IPv4 is used, with no IP options, the UDP/IP header will be 28 octets in size. This gives a total compound RTCP packet size of $S_c = 142 + 2*Nr$ octets.

The reduced-size RTCP packets will comprise just the CCFB packet, SRTCP trailer and authentication tag, and a UDP/IP header. It can be seen that these packets will be $S_{rs} = 62 + 2*Nr$ octets in size.

The RTCP reporting interval calculation ([RFC3550], Section 6.2) for a two-party session where both participants are senders, reduces to:

$$Trtcp = n * Srtcp / Brtcp$$

where $Srtcp = (S_c + N_{rs} * S_{rs}) / (1 + N_{rs})$ is the average RTCP packet size in octets, $Brtcp$ is the bandwidth allocated to RTCP in octets per second, and n is the number of participants in the RTP session (in this scenario, $n = 2$).

To ensure an RTCP report containing congestion control feedback is sent after every Nr frames of audio, it is necessary to set the RTCP reporting interval $Trtcp = Nr * T_f$, which when substituted into the previous gives $Nr * T_f = n * Srtcp / Brtcp$. Solving this to give the RTCP bandwidth, $Brtcp$, and expanding the definition of $Srtcp$ gives:

$$Brtcp = (n * (S_c + N_{rs} * S_{rs})) / (Nr * T_f * (1 + N_{rs})).$$

If we assume every report is a compound RTCP packet (i.e., $N_{rs} = 0$), the frame duration $T_f = 20ms$, and an RTCP report is sent for every second frame (i.e., 25 RTCP reports per second), this gives an RTCP feedback bandwidth, $Brtcp = 57kbps$. Increasing the frame duration, or reducing the frequency of reports, will reduce the RTCP bandwidth as shown in Table 1.

Tf (seconds)	Nr (frames)	rtcp_bw (kbps)
0.020	2	57.0
0.020	4	29.3
0.020	8	15.4
0.020	16	8.5
0.060	2	19.0
0.060	4	9.8
0.060	8	5.1
0.060	16	2.8

Table 1: RTCP bandwidth needed for VoIP feedback (compound reports only)

The final row of Table 1 (60ms frames, report every 16 frames) sends RTCP reports once per second, giving an RTCP bandwidth overhead of 2.8kbps.

The overhead can be reduced by sending some reports in reduced-size RTCP packets [RFC5506]. For example, if we alternate compound and reduced-size RTCP packets, i.e., $Nrs = 1$, the calculation gives the results shown in Table 2.

Tf (seconds)	Nr (frames)	rtcp_bw (kbps)
0.020	2	41.4
0.020	4	21.5
0.020	8	11.5
0.020	16	6.5
0.060	2	13.8
0.060	4	7.2
0.060	8	3.8
0.060	16	2.2

Table 2: Required RTCP bandwidth for VoIP feedback (alternating compound and non-compound reports)

The RTCP bandwidth needed for 60ms frames, reporting every 16 frames (once per second), can be seen to drop to 2.2kbps. This calculation can be repeated for other patterns of compound and reduced-size RTCP packets, feedback frequency, and frame duration, as needed.

Note: To achieve the RTCP transmission intervals above the RTP/SAVPF profile with $T_{rr_interval}=0$ is used, since even when using the

reduced minimal transmission interval, the RTP/SAVP profile would only allow sending RTCP at most every 0.11s (every third frame of video). Using RTP/SAVPF with `T_rr_interval=0` however is capable of fully utilizing the configured 5% RTCP bandwidth fraction.

3.2. Scenario 2: Point-to-Point Video Conference

Consider a point-to-point video call between two end systems. There will be four RTP flows in this scenario, two audio and two video, with all four flows being active for essentially all the time (the audio flows will likely use voice activity detection and comfort noise to reduce the packet rate during silent periods, but this does not cause the transmissions to stop).

Assume all four flows are sent in a single RTP session, each using a separate SSRC. The RTCP reports from the co-located audio and video SSRCs at each end point are aggregated [RFC8108], the optimisations in [RFC8861] are used, and RTCP congestion control feedback is sent [RFC8888].

As in Section 3.1, when all members are senders the RTCP reporting interval calculation in Section 6.2 and 6.3 of [RFC3550] and [RFC4585] reduces to:

$$\text{Trtcp} = n * \text{Srtcp} / \text{Brtcp}$$

where `n` is the number of members in the session, `Srtcp` is the average RTCP packet size in octets, and the `Brtcp` is the RTCP bandwidth in octets per second.

The average RTCP packet size, `Srtcp`, depends on the amount of feedback sent in each RTCP packet, on the number of members in the session, on the size of source description (RTCP SDES) information sent, and on the amount of congestion control feedback sent in each packet.

As a baseline, each RTCP packet will be a compound RTCP packet that contains an aggregate of a compound RTCP packet generated by the video SSRC and a compound RTCP packet generated by the audio SSRC. When the RTCP reporting group extensions are used, one of these SSRCs will be a reporting SSRC, to which the other SSRC will have delegated its reports. No reduced-size RTCP packets are sent.

The aggregated compound RTCP packet from the non-reporting SSRC will contain an RTCP SR packet, an RTCP SDES packet, and an RTCP RGRS packet. The RTCP SR packet contains the 28 octet header and sender information, but no report blocks (since the reporting is delegated). The RTCP SDES packet will comprise a header (4 octets), originating

SSRC (4 octets), a CNAME chunk, a terminating chunk, and any padding. If the CNAME follows [RFC7022] and [RFC8834] the CNAME chunk will be 18 octets in size, and will be followed by one octet of padding and one terminating null octet to align the SDES packet to a 32-bit boundary ([RFC3550], section 6.5), making the SDES packet 28 octets in size. The RTCP RGRS packet will be 12 octets in size. This gives a total of $28 + 28 + 12 = 68$ octets.

The aggregated compound RTCP packet from the reporting SSRC will contain an RTCP SR packet, an RTCP SDES packet, and an RTCP congestion control feedback packet. The RTCP SR packet will contain two report blocks, one for each of the remote SSRCs (the report for the other local SSRC is suppressed by the reporting group extension), for a total of $28 + (2 * 24) = 76$ octets. The RTCP SDES packet will comprise a header (4 octets), originating SSRC (4 octets), a CNAME chunk, an RGRP chunk, a terminating chunk, and any padding. If the CNAME follows [RFC7022] and [RFC8834] it will be 18 octets in size. The RGRP chunk similarly comprises 18 octets, and 3 octets of padding are needed, for a total of 48 octets. The RTCP congestion control feedback (CCFB) report comprises an 8-octet RTCP header and SSRC, a 4-octet report timestamp, and for each of the remote audio and video SSRCs, an 8-octet report header, and 2 octets per packet reported upon, and padding to a 4-octet boundary if needed; that is $8 + 4 + 8 + (2 * N_v) + 8 + (2 * N_a)$ where N_v is the number of video packets per report, and N_a is the number of audio packets per report.

The complete compound RTCP packet contains the RTCP packets from both the reporting and non-reporting SSRCs, an SRTCP trailer and authentication tag, and a UDP/IPv4 header. The size of this RTCP packet is therefore: $262 + (2 * N_v) + (2 * N_a)$ octets. Since the aggregate RTCP packet contains reports from two SSRCs, the RTCP packet size is halved before use [RFC8108]. Accordingly, the size of the RTCP packets is:

$$Srtcp = (262 + (2 * N_v) + (2 * N_a)) / 2$$

How many RTP packets does the RTCP XR congestion control feedback packet, included in these compound RTCP packets, report on? That is, what are the values of N_v and N_a ? This depends on the RTCP reporting interval, $Trtcp$, the video bit rate and frame rate, R_f , the audio bit rate and framing interval, and whether the receiver chooses to send congestion control feedback in each RTCP packet it sends.

To simplify the calculation, assume it is desired to send one RTCP report for each frame of video received (i.e., $Trtcp = 1 / R_f$) and to include a congestion control feedback packet in each report. Assume that video has constant bit rate and frame rate, and that each frame of packet has to fit into a 1500 octet MTU. Further, assume that the

audio takes negligible bandwidth, and that the audio framing interval can be varied within reasonable bounds, so that an integral number of audio frames align with video frame boundaries.

Table 3 shows the resulting values of N_v and N_a , the number of video and audio packets covered by each congestion control feedback report, for a range of data rates and video frame rates, assuming congestion control feedback is sent once per video frame. The table also shows the result of inverting the RTCP reporting interval calculation to find the corresponding RTCP bandwidth, B_{rtcp} . The RTCP bandwidth is given in kbps and as a fraction of the data rate.

It can be seen that, for example, with a data rate of 1024 kbps and video sent at 30 frames-per-second, the RTCP congestion control feedback report sent for each video frame will include reports on 3 video packets and 2 audio packets. The RTCP bandwidth needed to sustain this reporting rate is 127.5 kbps (12% of the data rate). This assumes an audio framing interval of 16.67ms, so that two audio packets are sent for each video frame.

Data Rate (kbps)	Video Frame Rate: R_f	Video Packets per Report: N_v	Audio Packets per Report: N_a	Required RTCP bandwidth: B_{rtcp} (kbps)
100	8	1	6	34.5 (34%)
200	16	1	3	67.5 (33%)
350	30	1	2	125.6 (35%)
700	30	2	2	126.6 (18%)
700	60	1	1	249.4 (35%)
1024	30	3	2	127.5 (12%)
1400	60	2	1	251.2 (17%)
2048	30	6	2	130.3 (6%)
2048	60	3	1	253.1 (12%)
4096	30	12	2	135.9 (3%)
4096	60	6	1	258.8 (6%)

Table 3: Required RTCP bandwidth, reporting on every frame

Use of reduced size RTCP [RFC5506] would allow the SR and SDES packets to be omitted from some reports. These "reduced-size" RTCP packets would contain an RTCP RGRS packet from the non-reporting SSRC, and an RTCP SDES RGRP packet and a congestion control feedback packet from the reporting SSRC. This will be $12 + 28 + 12 + 8 + 2*N_v + 8 + 2*N_a$ octets, plus the SRTCP trailer and authentication tag, and a UDP/IP header. That is, the size of the reduced-size packets would be $(110 + 2*N_v + 2*N_a)/2$ octets. Repeating the analysis above, but

alternating compound and reduced-size reports gives results as shown in Table 4.

Data Rate (kbps)	Video Frame Rate: Rf	Video Packets per Report: Nv	Audio Packets per Report: Na	Required RTCP bandwidth: Brtcp (kbps)
100	8	1	6	24.1 (24%)
200	16	1	3	46.8 (23%)
350	30	1	2	86.7 (24%)
700	30	2	2	87.7 (12%)
700	60	1	1	171.6 (24%)
1024	30	3	2	88.6 (8%)
1400	60	2	1	173.4 (12%)
2048	30	6	2	91.4 (4%)
2048	60	3	1	175.3 (8%)
4096	30	12	2	97.0 (2%)
4096	60	6	1	180.9 (4%)

Table 4: Required RTCP bandwidth, reporting on every frame, with reduced-size reports

The use of reduced-size RTCP gives a noticeable reduction in the needed RTCP bandwidth, and can be combined with reporting every few frames rather than every frame. Overall, it is clear that the RTCP overhead can be reasonable across the range of data and frame rates, if RTCP is configured carefully.

4. Discussion and Conclusions

Practical systems will generally send some non-media traffic on the same path as the media traffic. This can include STUN/TURN packets to keep-alive NAT bindings [RFC8445], WebRTC Data Channel packets [RFC8831], etc. Such traffic also needs congestion control, but the means by which this is achieved is out of scope of this memo.

RTCP as it is currently specified cannot be used to send per-packet congestion feedback with reasonable overhead.

RTCP can, however, be used to send congestion feedback on each frame of video sent, provided the session bandwidth exceeds a couple of megabits per second (the exact rate depending on the number of session participants, the RTCP bandwidth fraction, and what RTCP extensions are enabled, and how much detail of feedback is needed). For lower rate sessions, the overhead of reporting on every frame becomes high, but can be reduced to something reasonable by sending

reports once per N frames (e.g., every second frame), or by sending reduced-size RTCP reports in between the regular reports.

If it is desired to use RTCP in something close to its current form for congestion feedback in WebRTC, the multimedia congestion control algorithm needs to be designed to work with feedback sent every few frames, since that fits within the limitations of RTCP. The provided feedback will be more detailed than just an acknowledgement, however, and will provide a loss bitmap, relative arrival time, and received ECN marks, for each packet sent. This will allow congestion control that is effective, if slowly responsive, to be implemented (there is guidance on providing effective congestion control in Section 3.1 of [RFC8085]).

The format described in [RFC8888] seems sufficient for the needs of congestion control feedback. There is little point optimising this format: the main overhead comes from the UDP/IP headers and the other RTCP packets included in the compound packets, and can be lowered by using the [RFC5506] extensions and sending reports less frequently. The use of header compression [RFC2508], [RFC3545], [RFC5795] can also be beneficial.

Further study of the scenarios of interest is needed, to ensure that the analysis presented is applicable to other media topologies [RFC7667], and to sessions with different data rates and sizes of membership.

5. Security Considerations

An attacker that can modify or spoof RTCP congestion control feedback packets can manipulate the sender behaviour to cause denial of service. This can be prevented by authentication and integrity protection of RTCP packets, for example using the secure RTP profile [RFC3711][RFC5124], or by other means as discussed in [RFC7201].

6. IANA Considerations

There are no actions for IANA.
