

Data Link Layer (I)

Networked Systems Architecture 3
Lecture 7

UNIVERSITY
of
GLASGOW

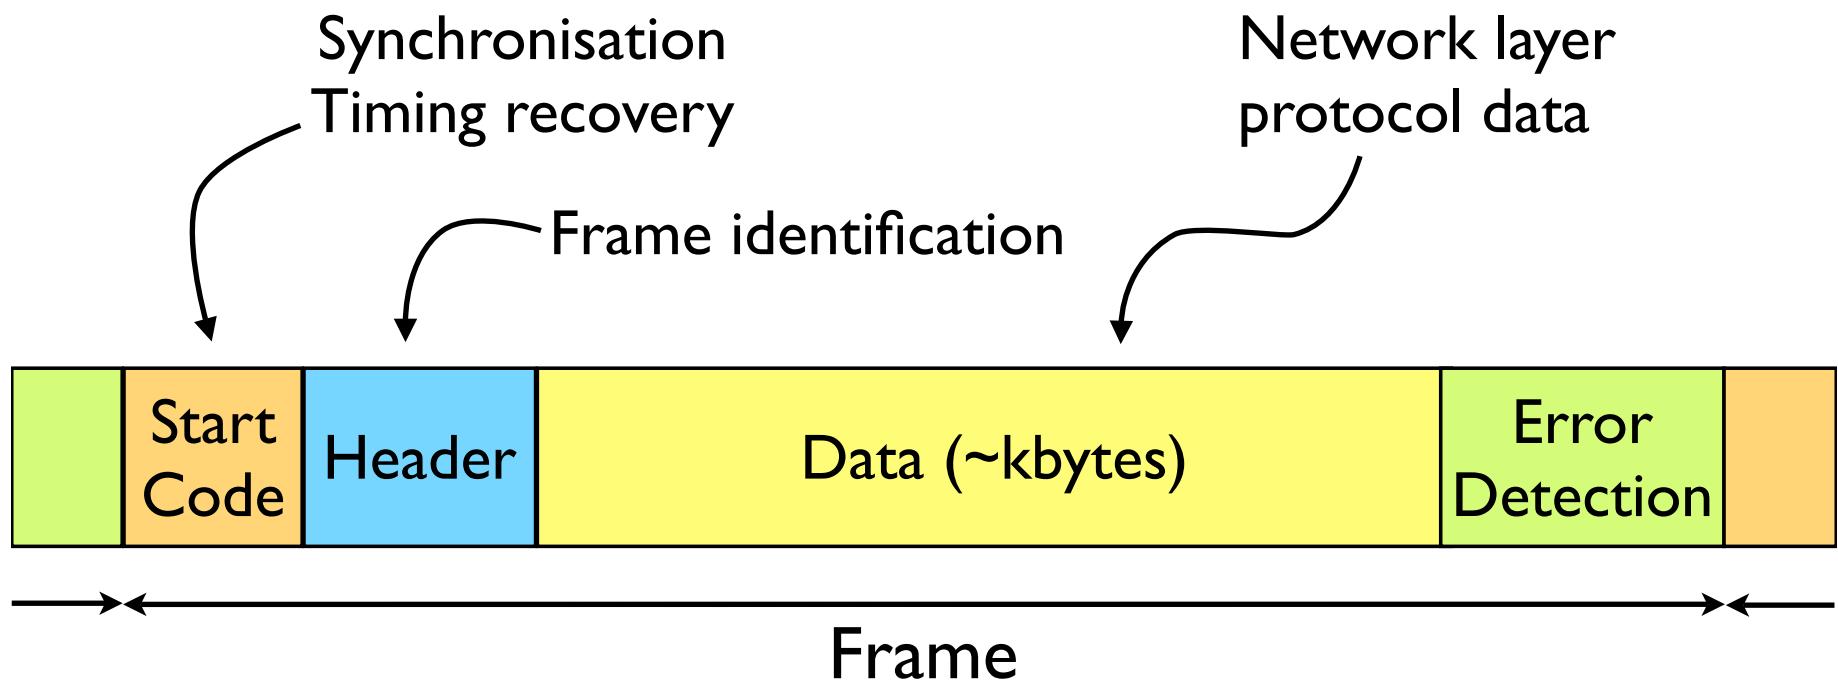

Purpose of Data Link Layer

- Arbitrate access to the physical layer
 - Structure and frame the raw bits
 - Provide flow control
 - Detect and correct bit errors
 - Perform media access control
- Turn the raw bit stream into a structured communications channel

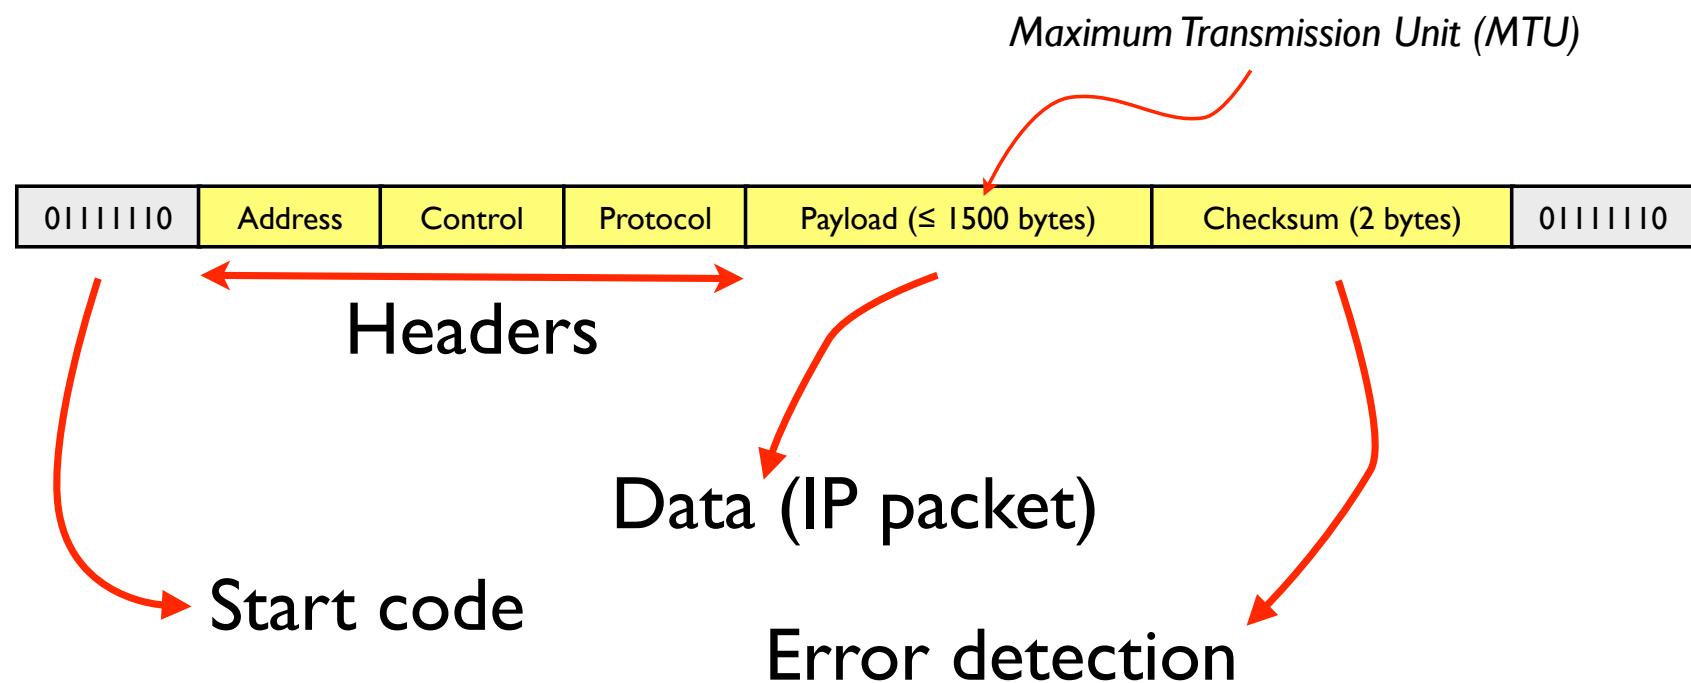

Framing and Synchronisation

- Physical layer provides unreliable raw bit stream
 - Bits might be corrupted
 - Timing can be disrupted
- Data link layer must correct these problems
 - Break the raw bit stream into *frames*
 - Transmit and repair individual frames
 - Limit scope of any transmission errors

Frame Structure

Example: PPP Frame

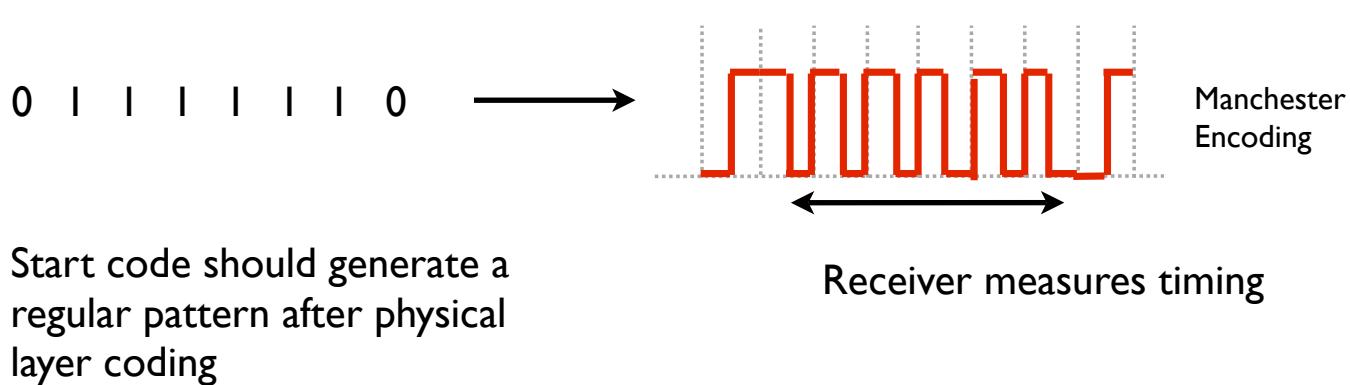

Synchronisation (I)

- How to detect the start of a message?
 - Leave gaps between frames
 - Problem – physical layer typically doesn't guarantee timing (clock skew, etc.)
 - Precede each frame with a length field
 - What if that length is corrupted? How to find next frame?
 - Add a special *start code* to beginning of frame
 - A unique bit pattern that *only* occurs at the start of each frame
 - Enables synchronisation after error – wait for next start code, begin reading frame headers

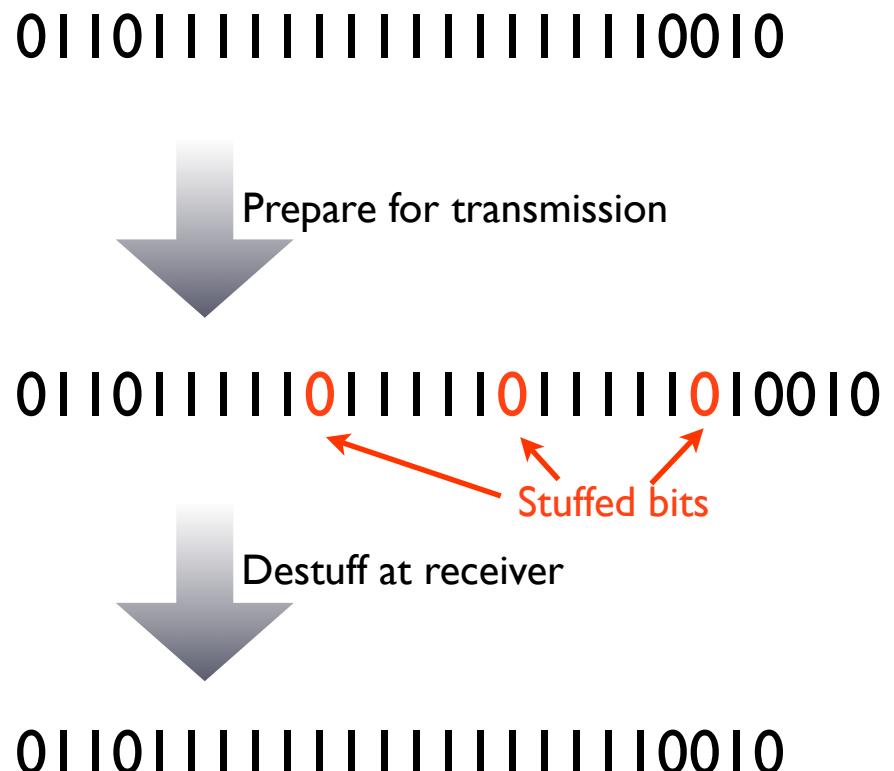

Synchronisation (2)

- What makes a good start code?
 - Must not appear in the frame headers, data, or error detecting code
 - Must allow timing recovery

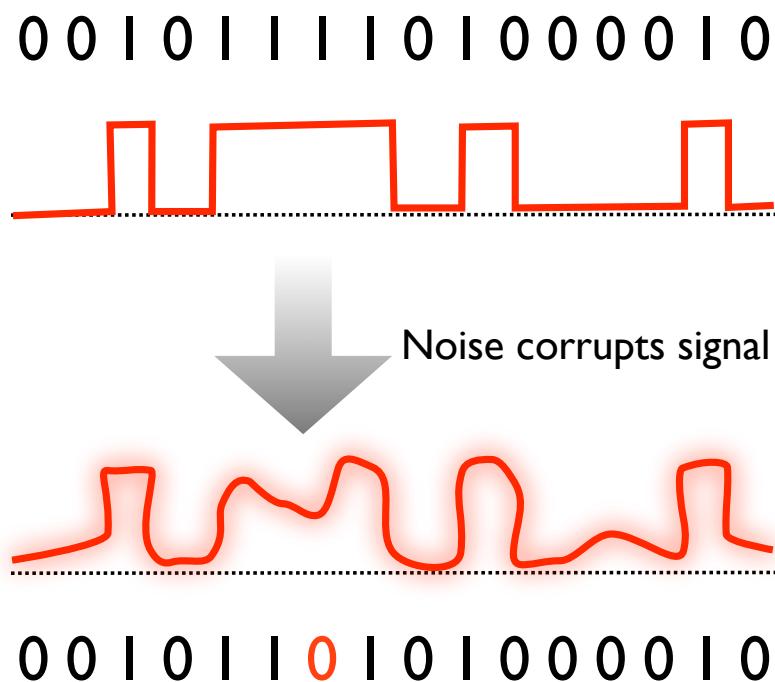

Synchronisation (3)

- What if the start code appears in the data?
- Use *bit stuffing* to give a transparent channel
 - $1111 \rightarrow 11110 \rightarrow 1111$
 - Can also use byte stuffing – double up the start code byte if it appears in the data

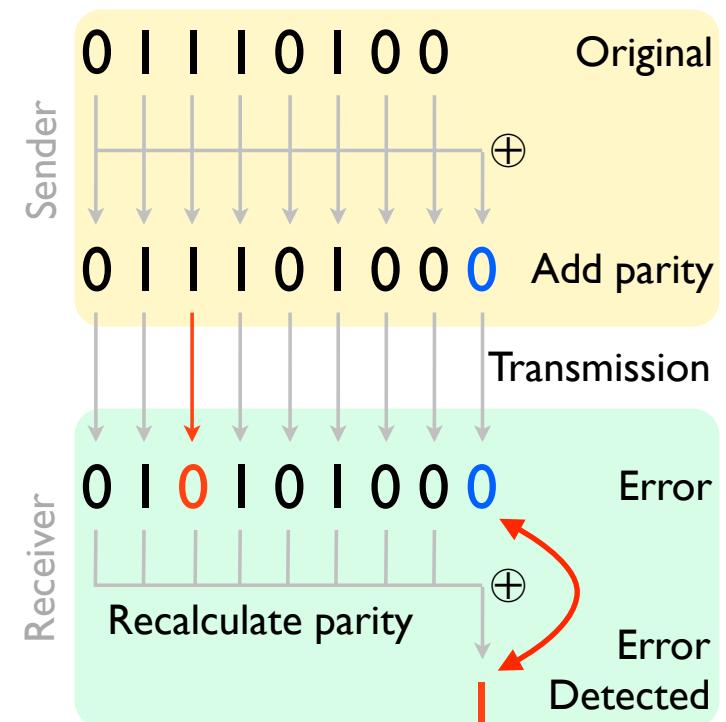

Error Detection

- Noise and interference at the physical layer can cause bit errors
 - Rare in wired links, common in wireless systems
- Add *error detecting code* to each packet

Parity Codes

- Simplest error detecting code
- Calculate *parity* of the data
 - How many 1 bits are in the data?
 - An odd number → parity 0
 - An even number → parity 1
 - Parity bit is the XOR (“ \oplus ”) of data bits
- Transmit parity with the data, check at receiver

The Internet Checksum

```
#include <stdint.h>

// Internet checksum algorithm. Assumes
// data is padded to a 16-bit boundary.
uint16_t
internet_cksum(uint16_t *buf, int buflen)
{
    uint32_t sum = 0;

    while (buflen--) {
        sum += *(buf++);
        if (sum & 0xffff0000) {
            // Carry occurred, wrap around
            sum &= 0x0000ffff;
            sum++;
        }
    }
    return ~(sum & 0x0000ffff);
}
```

- Sum data values, send as **checksum** in each frame
 - Internet protocol uses a 16 bit ones complement checksum
- Receiver recalculates, mismatch → bit error
- Better error detection than parity code

Other Error Detecting Codes

- Parity codes and checksums relatively weak
 - Simple to implement
 - Undetected errors reasonably likely
- More powerful error detecting codes exist
 - *Cyclic redundancy code (CRC)*
 - More complex → fewer undetected errors
 - (see recommended reading for details)

Error Correction

- How to correct bit errors?
 - Forward error correction (FEC)
 - Sender includes additional information in the initial transmission, allowing receiver to correct the error itself
 - Automatic repeat request (ARQ)
 - Receiver contacts sender to request a retransmission of the incorrect data

Forward Error Correction

- Extend error detecting codes to *correct* errors
 - Sender transmits error correcting code
 - Additional data within each frame
 - Additional frames
 - Allows receiver to correct (some) errors without contacting sender

FEC: Within a Frame

- Example: Hamming code
 - Send n data bits and k check bits every word
 - Check bits are sent as bits 1, 2, 4, 8, 16, ...
 - Each check bit codes parity for some data bits
 - $b_1 = b_3 \oplus b_5 \oplus b_7 \oplus b_9 \oplus b_{11} \dots$
 - $b_2 = b_3 \oplus b_6 \oplus b_7 \oplus b_{10} \oplus b_{11} \oplus b_{14} \oplus b_{15} \dots$
 - $b_4 = b_5 \oplus b_6 \oplus b_7 \oplus b_{12} \oplus b_{13} \oplus b_{14} \oplus b_{15} \dots$
 - i.e. starting at check bit i , check i bits, skip i bits, repeat

Character	ASCII	Hamming Code
H	1001000	<u>00</u> 1 <u>1</u> 001 <u>0</u> 000
a	1100001	<u>1</u> 0 <u>1</u> 1 <u>00</u> 1 <u>00</u> 1
m	1101101	<u>1</u> 1 <u>1</u> 0 <u>101</u> <u>0</u> 101
m	1101101	<u>1</u> 1 <u>1</u> 0 <u>101</u> <u>0</u> 101
i	1101001	<u>0</u> 1 <u>1</u> 0 <u>101</u> <u>1</u> 001
n	1101110	<u>0</u> 1 <u>1</u> 0 <u>101</u> <u>0</u> 110
g	1100111	<u>1</u> 1 <u>1</u> 1 <u>100</u> <u>1</u> 111
	0100000	<u>1</u> 0 <u>0</u> 1 <u>100</u> <u>0</u> 000
c	1100011	<u>1</u> 1 <u>1</u> 1 <u>100</u> <u>0</u> 011
o	1101111	<u>0</u> 0 <u>1</u> 0 <u>101</u> <u>1</u> 111
d	1100100	<u>1</u> 1 <u>1</u> 1 <u>100</u> <u>1</u> 100
e	1100101	<u>0</u> 0 <u>1</u> 1 <u>100</u> <u>0</u> 101

FEC: Within a Frame

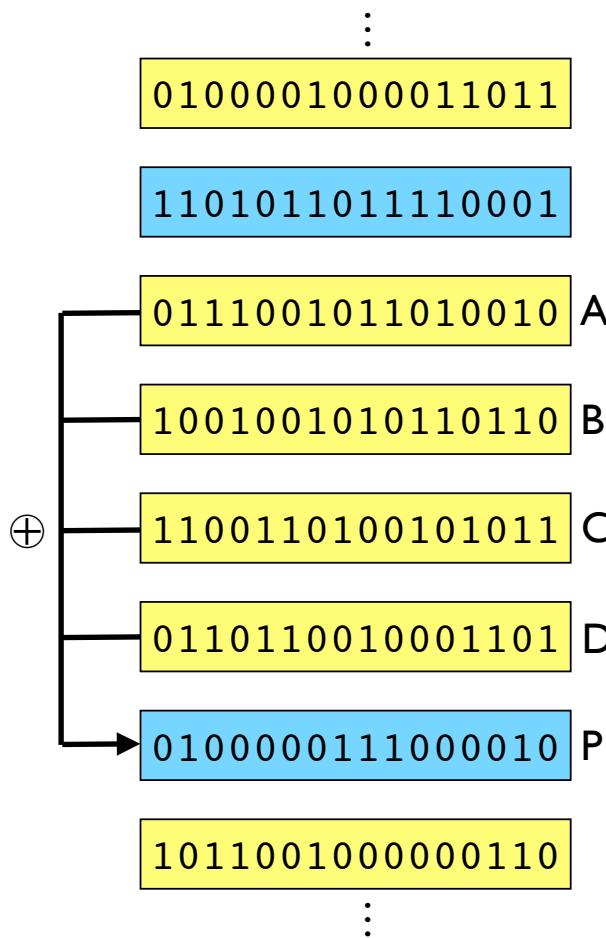

- On reception:

- Set *counter* = 0
- Recalculate each check bit, k , in turn ($k = 1, 2, 4, 8, \dots$); if incorrect, *counter* += k
- If (*counter* == 0) {
 no errors
} else {
 bit *counter* is incorrect
}

- Allows correction of all single bit errors

Character	ASCII	Hamming Code
H	1001000	<u>0011</u> 001 <u>0000</u>
a	1100001	<u>1011</u> 100 <u>1001</u>
m	1101101	<u>1110</u> 101 <u>0101</u>
m	1101101	<u>1110</u> 101 <u>0101</u>
i	1101001	<u>0110</u> 101 <u>1001</u>
n	1101110	<u>0110</u> 101 <u>0110</u>
g	1100111	<u>1111</u> 100 <u>1111</u>
	0100000	<u>1001</u> 100 <u>0000</u>
c	1100011	<u>1111</u> 100 <u>0011</u>
o	1101111	<u>0010</u> 101 <u>1111</u>
d	1100100	<u>1111</u> 100 <u>1100</u>
e	1100101	<u>0011</u> 100 <u>0101</u>

FEC: Error Correcting Frames

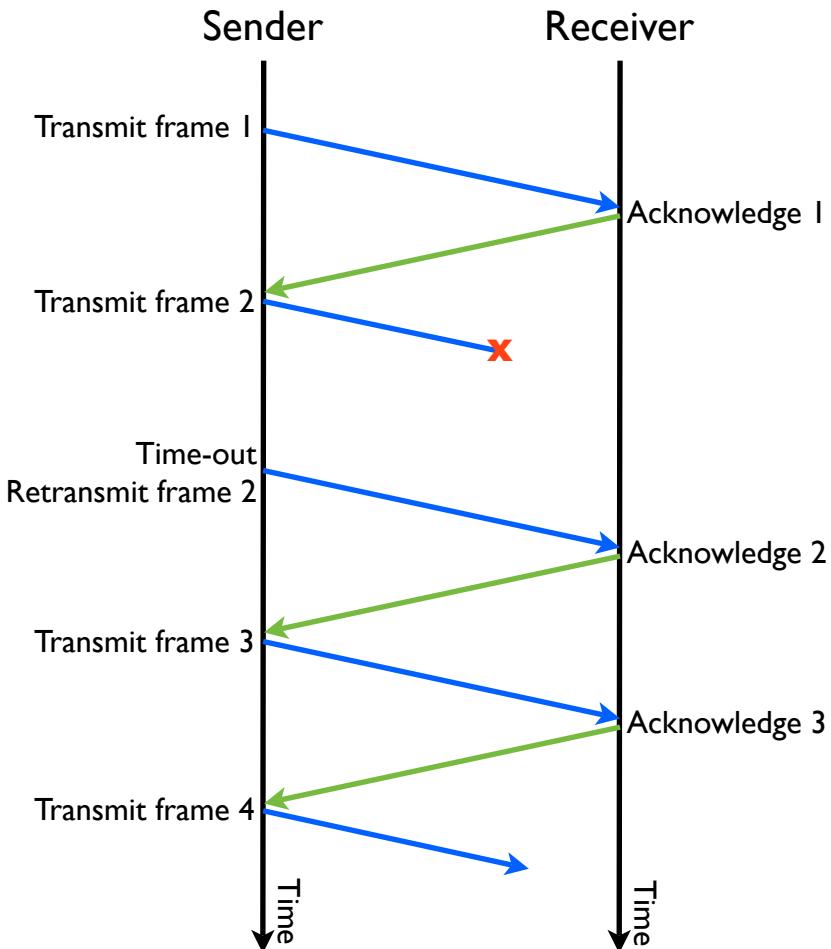

- Alternative: send extra error correcting frames
- Example: packet level parity
 - Send k parity packets every n data packets
 - Each parity packet is \oplus of the data packets
 - Correct loss or error since \oplus commutative
 - E.g. if B in error, repair $B = A \oplus C \oplus D \oplus P$

Atomtic Repeat Request

- Each frame includes a sequence number
- Receiver sends *acknowledgements* as it receives data frames
 - Can be sent as dedicated acknowledgement frames, or piggybacked onto returning data frames
 - Can be a positive acknowledgement (“I got frame n ”) or a negative acknowledgement (“frame n is missing”)

Stop and Wait

- Simplest ARQ scheme:
 - Transmit a frame
 - Await positive acknowledgement from receiver
 - If no acknowledgement after some time out, retransmit frame
- Limitation:
 - One frame outstanding on link → limited performance on links with high bandwidth×delay product

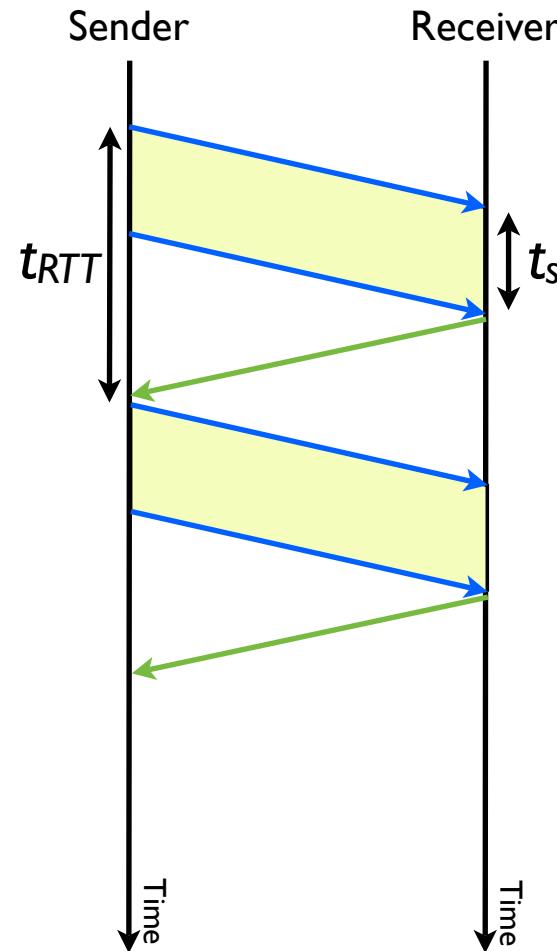

Bandwidth×Delay Product

- Signal has limited speed:
 - $\approx 2.3 \times 10^8$ m/s in electrical cable,
 $\approx 2.0 \times 10^8$ m/s in optical fibre
- Determines propagation delay for the link
 - Baseline value – queuing will lead to higher delays
- Example link capacity:
 - Glasgow – London (~670km) → 3ms propagation delay
 - Assume a 10 gigabit per second link speed
 - 0.003 seconds \times 10000000000 bits/second = 30000000 bits link capacity (~3.5 Mbytes of data in flight)

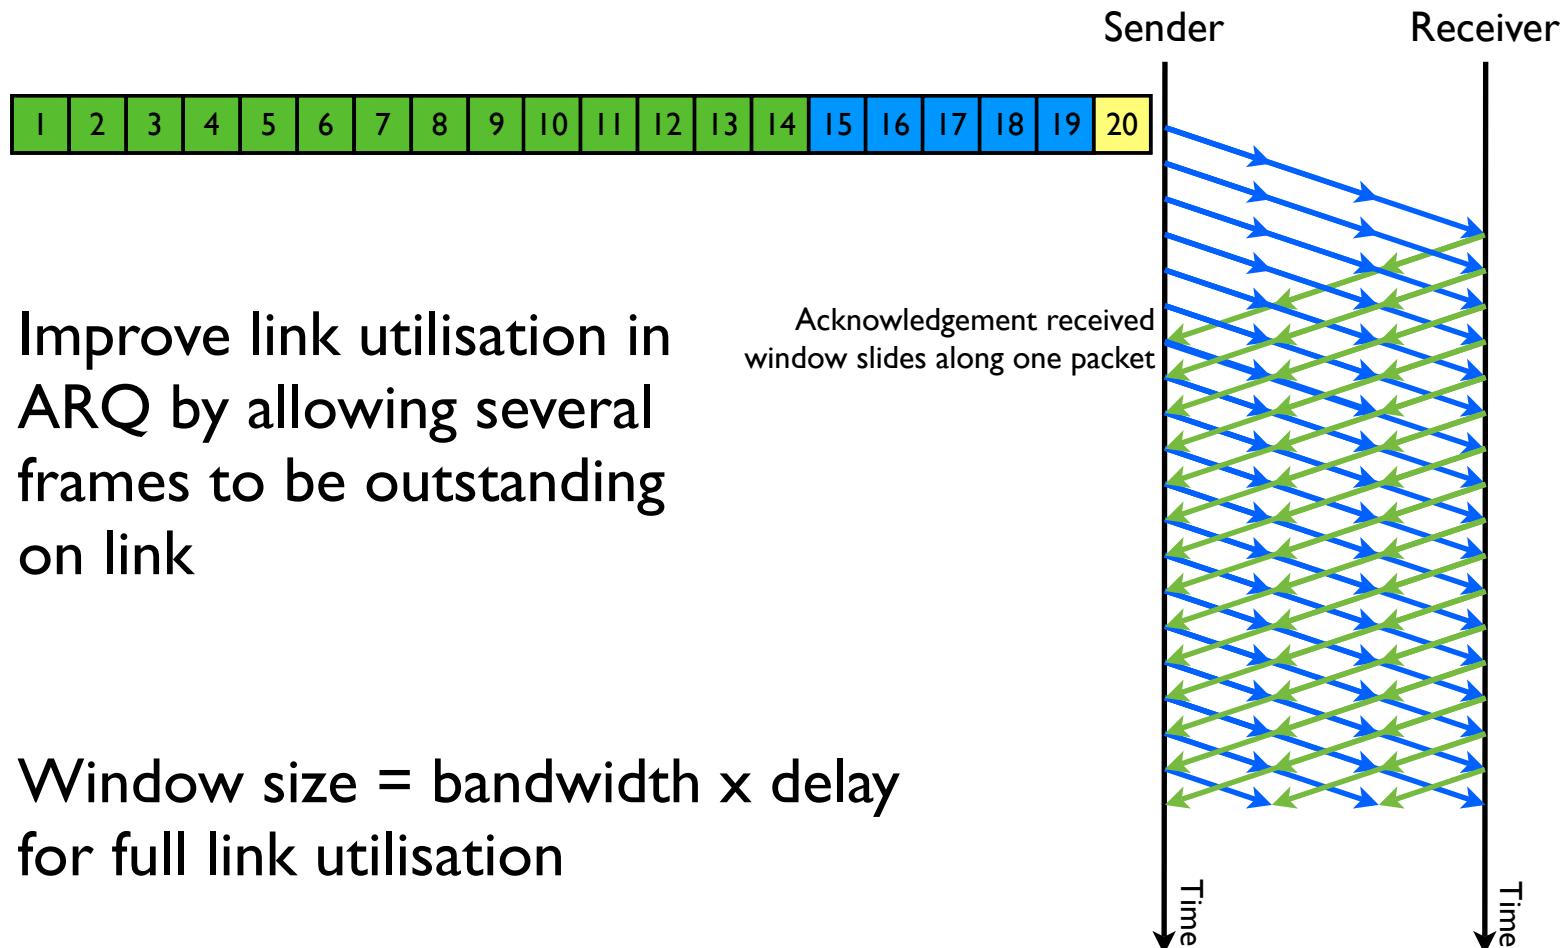

Bandwidth \times delay = link capacity

Link Utilisation

- Assume it takes time, t_s , to serialise a frame onto link
 - $t_s = (\text{frame size}) / (\text{link bandwidth})$
- Acknowledgement returns t_{RTT} seconds later
- Utilisation, $U = t_s / t_{RTT}$
 - Desire link fully utilised: $U \sim 1.0$
 - But $U \ll 1.0$ for stop-and-wait protocol

Sliding Window Protocol

Sliding Window Protocol

- Stop-and-wait acceptable in LAN
 - Bandwidth delay product small, since RTT tiny
 - Reasonably efficient
- Variants on sliding window protocol required for wide area ARQ
 - How to choose window size? What is acknowledged?
 - Example: TCP congestion control

Questions?
