

Bridging

Networked Systems 3 Lecture 7

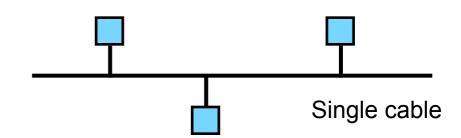

Lecture Outline

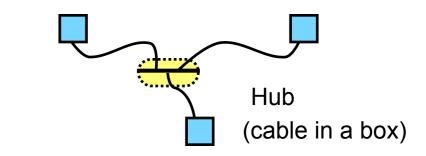

- Link-layer topology evolution
 - Hubs
 - Bridges
- Basic bridge operation
- Loops in bridged networks
- Spanning tree protocol

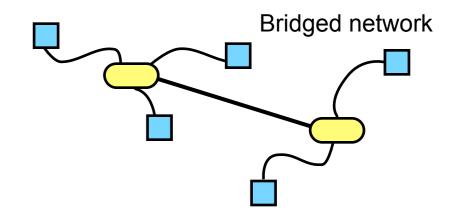

Bridging

• Link-layer topology evolution:

- Media access control assumes a single link – on wired networks, a single cable
- Vulnerable to cable damage
- A hub is a cable in a box no intelligence
- Damage to vulnerable cables disconnects only a single host, rather than partitioning the network
- A bridge is an intelligent device
- Understands the media access control protocol – joins multiple links together

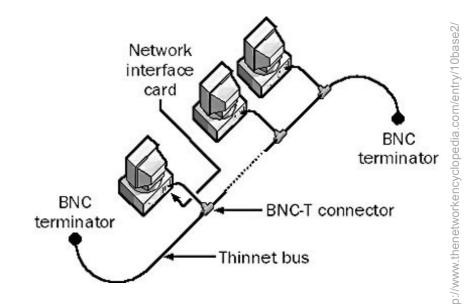

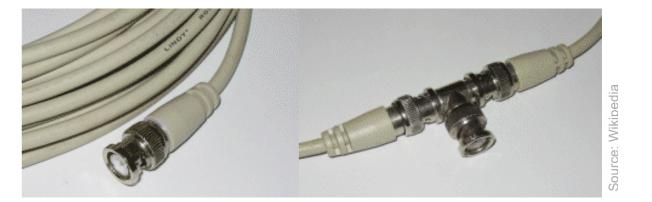

Link Layer Topology Evolution

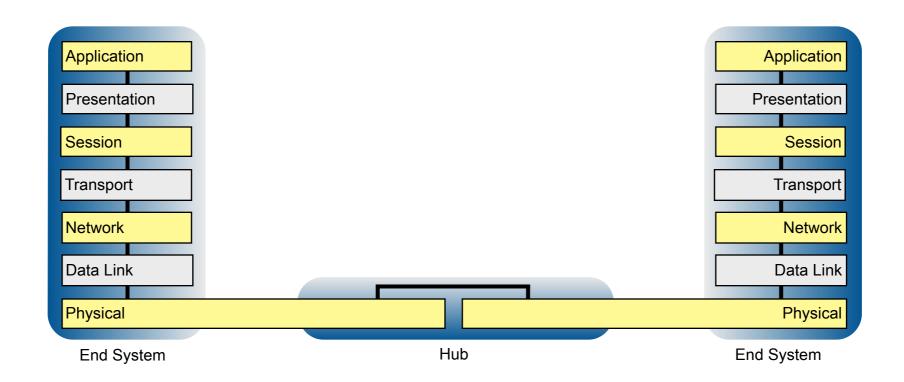

- Media access control assumes a single link
 - Limits scalability of a system
 - Vulnerable to cable damage
 - Vulnerable to disconnection

Example: 10base2 Ethernet

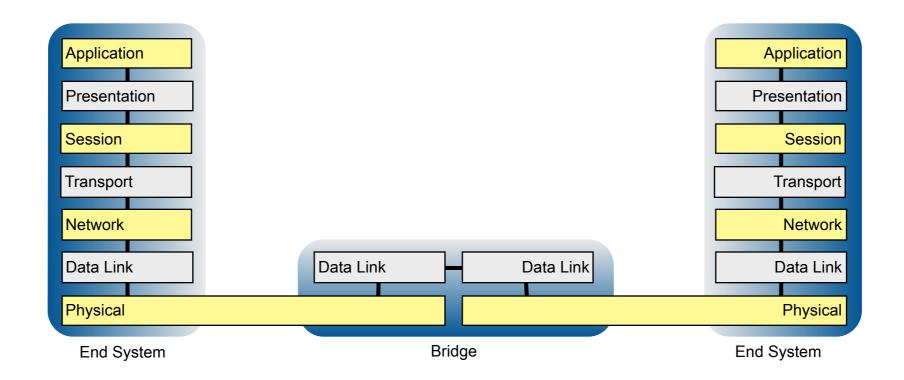

Extending Link-layer Networks: Hubs

A hub is a physical layer interconnection of links

- Equivalent to running a longer cable
- Doesn't improve scalability of the network but can make physical interconnection of cables/devices easier
- Largely obsolete replaced by data link layer bridges

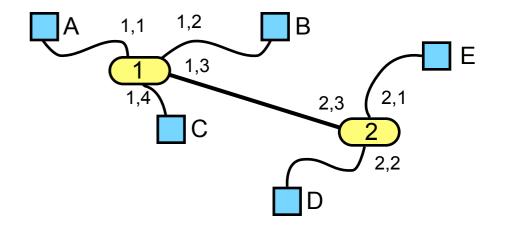

Extending Link-layer Networks: Bridging

- A bridge is a data link layer device to interconnect physical networks
 - An intelligent device: understands and processes data link layer frames, identifies location of hosts, forwards only those frames of interest
 - Automatic needs zero configuration
 - Example: "Ethernet switch"

Learn addresses on each link

- Observe source addresses of packets
- Soft state time-out allows for graceful response to failure and node mobility

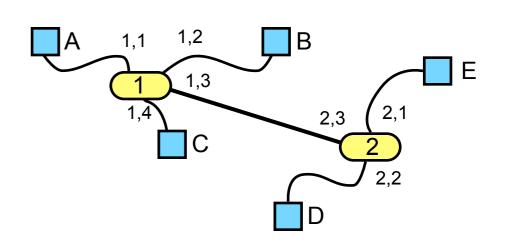

Forward traffic as appropriate

- Unicast traffic based on host locations (hash from address to destination link, flooding packets to unknown hosts)
- Multicast based on group membership
- Broadcast traffic

Bridge 1 state

Link	Host
1,1	
1,2	
1,3	
1,4	

Bridge 2 state

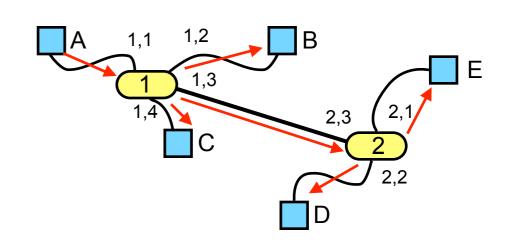

Link	Host
2,1	
2,2	
2,3	

State of network on initialisation:

Neither bridge knows location of any hosts

Bridge 1 state

Link	Host
1,1	Α
1,2	
1,3	
1,4	

Bridge 2 state

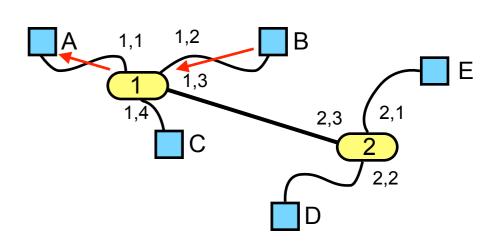

Link	Host
2,1	
2,2	
2,3	Α

Host A sends packet destined for host B

- Received at bridge 1, which records location of host A
- Location of host B unknown, so bridge 1 floods packet to all outgoing links
- Also received at bridge 2, which doesn't know location of host B, so floods the packet to all outgoing links; records location of host A

Bridge 1 state

Link	Host
1,1	Α
1,2	В
1,3	
1,4	

Bridge 2 state

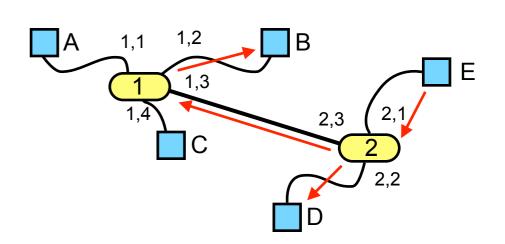

Link	Host
2,1	
2,2	
2,3	Α

Host B responds with packet destined for host A

- Received at bridge 1, which knows location of host A, and can directly forward the packet without flooding
- Bridge 1 records location of host B

Bridge 1 state

Link	Host
1,1	Α
1,2	В
1,3	Е
1,4	

Bridge 2 state

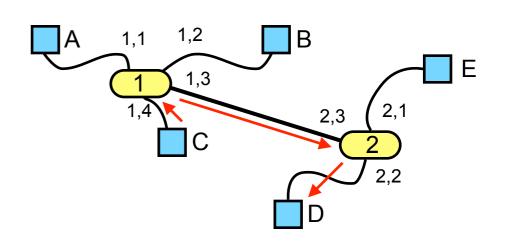

Link	Host
2,1	Ш
2,2	
2,3	A

Some time later, host E sends packet destined for host B

- Received at bridge 2, which doesn't know location of B and so floods packet to all outgoing links; records the location of host E
- Received at bridge 1, which does know how to reach host B, and directly forwards the packet; records how to reach host E

Bridge 1 state

Link	Host
1,1	Α
1,2	В
1,3	D,E
1,4	С

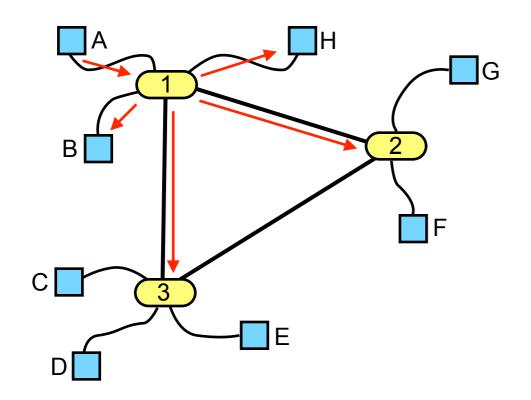

Bridge 2 state

Link	Host
2,1	Е
2,2	D
2,3	A,B,C

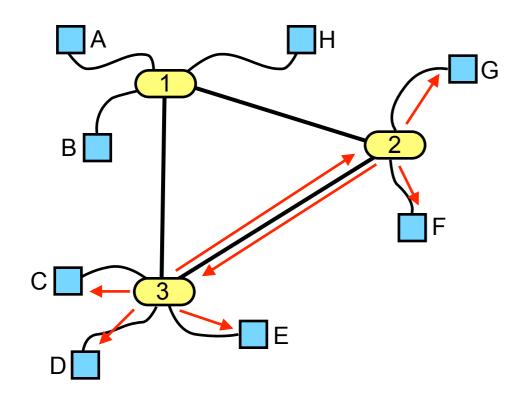

Over time, bridges learn location of every host, and can forward all packets without flooding

- Learning protocol finds all hosts without needing any configuration
- Flooding ensures connectivity is maintained, even when protocol has no knowledge – performance is never worse than a hub, even when flooding
- Use of soft state and timeouts ensures knowledge of failed or disconnected devices disappears
- Poor scalability every bridge knows about every host

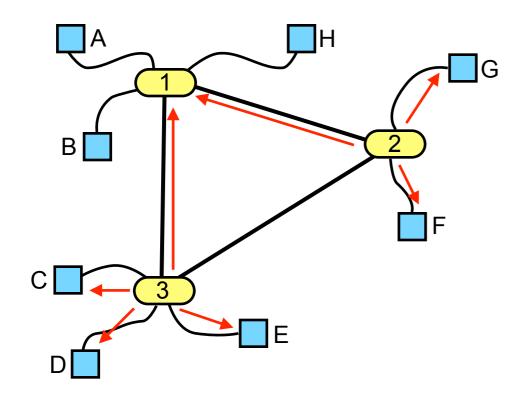

Host A sends packet to host X, that does not exist

 Received at bridge 1, which doesn't know location of X, so floods packet to all outgoing links

Host A sends packet to host X, that does not exist

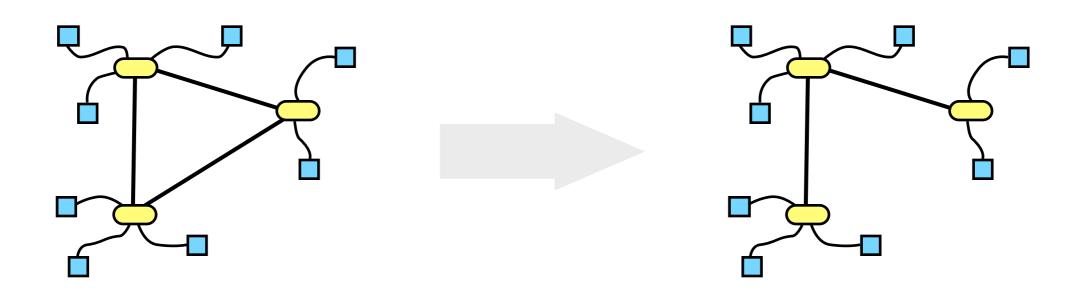

- Received at bridge 1, which doesn't know location of X, so floods packet to all outgoing links
- Received at bridges 2 and 3, which also don't know location of X, and so flood packet to all outgoing links

Host A sends packet to host X, that does not exist

- Received at bridge 1, which doesn't know location of X, so floods packet to all outgoing links
- Received at bridges 2 and 3, which also don't know location of X, and so flood packet to all outgoing links
- Packets cross in transit between bridges 2 and 3 – causing a loop unless countermeasures are taken

- Solution: build a spanning tree over the network, forward packets along this tree
 - Model network as an undirected graph, G
 - A spanning tree over that graph is a tree comprising all the vertices and some of the edges of G
 - Edges are removed to eliminate loops, leaving minimal set of edges that still connect all vertices

Spanning Tree Algorithm

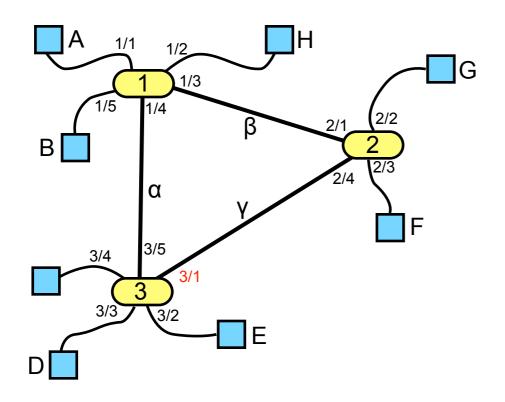

- Distributed algorithm to build spanning tree developed by Radia Perlman
 - Each bridge has a globally unique address
 - Bridge with numerically lowest address is the root bridge

Source: Sun Microsystems

- Each bridge periodically informs it's neighbours what it thinks is address of the root bridge –
 potentially making them update what they think it the root address
- Determine root port (port with shortest path to root bridge) of each bridge, except the root bridge
- For each LAN, select *designated bridge* for the LAN (this is the bridge with the shortest path to the root bridge; tie-break based on address)
 - The port connecting the designated bridge to the LAN is a designated port
- Enable all root ports and all designated ports, and disable all other ports forward traffic using only the enabled ports

Spanning Tree Algorithm

Bridge 1 is the *root bridge* (lowest address)

The root ports are 2/1 and 3/5

The designated bridges are:

- Bridge 1 for hosts A, B, and H and links α and β
- Bridge 2 for hosts F and G and link γ
- Bridge 3 for hosts C, D, and E

The designated ports are:

- Bridge 1: 1/1, 1/2, 1/3, 1/4, and 1/5
- Bridge 2: 2/2, 2/3, and 2/4
- Bridge 3: 3/2, 3/3, and 3/4

Port 3/1 is neither a root or designated port and is disabled, all others are enabled

Algorhyme

"I think that I shall never see A graph more lovely than a tree.

A tree whose crucial property Is loop-free connectivity.

First the Root must be selected. By ID it is elected.

Least cost paths from Root are traced. In the tree these paths are placed.

A mesh is made by folks like me. Then bridges find a spanning tree."

R. Perlman, "An algorithm for distributed computation of a spanning tree in an extended LAN", Proc. ACM SIGCOMM '85, Vancouver, BC, Canada, September 1985, DOI: 10.1145/319056.319004. http://dl.acm.org/citation.cfm?id=319004
